uniform distributions etc.

## Confidence Intervals

Defn let  $x_1, x_2, \dots, x_n$  be a sample on a random variable  $X$ , where  $X$  has p.d.f.  $f(x; \theta), \theta \in \Omega$ .

let  $0 < \alpha < 1$  be specified. Let

$L = L(x_1, \dots, x_n)$  and  $U = U(x_1, \dots, x_n)$  be two statistics. We say that the interval  $(L, U)$  is  $(1 - \alpha) 100\%$  confidence interval for  $\theta$  if

$$1 - \alpha = P_{\theta}(\theta \in (L, U)).$$

Once the sample is drawn, the realized  
value of the confidence interval is  $(l, u)$ , an  
interval of real numbers. Therefore,  $\theta$  either  
belongs to  $(l, u)$  or it does not.

Once the sample is drawn, the realized  
value of the confidence interval is  $(l, u)$ , an  
interval of real numbers. Therefore,  $\theta$  either  
belongs to  $(l, u)$  or it does not.

Therefore, we could think of confidence interval  
in terms of Bernoulli trials with  $p = 1 - \alpha$ .

Once the sample is drawn, the realized  
value of the confidence interval is  $(l, u)$ , an  
interval of real numbers. Therefore,  $\theta$  either  
belongs to  $(l, u)$  or it does not.

Therefore, we could think of confidence interval  
in terms of Bernoulli trials with  $p = 1 - \alpha$ .

If one makes  $M$   $(1 - \alpha) 100\%$  confidence intervals  
then we expect that  $(1 - \alpha) \cdot M$ . of them will  
contain  $\theta$ .

## Example Confidence interval for $\mu$ under normality

Suppose  $X_1, X_2, \dots, X_n$  are  $N(\mu, \sigma^2)$  distributed.

Let  $\bar{X}$  and  $S^2$  denote the sample mean and sample variance respectively.

We proved that  $T = (\bar{X} - \mu) / (S/\sqrt{n})$  has a t-distribution with  $n$  degrees of freedom.

## Example Confidence interval for $\mu$ under normality

Suppose  $X_1, X_2, \dots, X_n$  are  $N(\mu, \sigma^2)$  distributed.

Let  $\bar{X}$  and  $S^2$  denote the sample mean and sample variance respectively.

We proved that  $T = (\bar{X} - \mu) / (S/\sqrt{n})$  has a t-distribution with  $n$  degrees of freedom.

The random variable  $T$  is called our Pivot r.v.

## Example

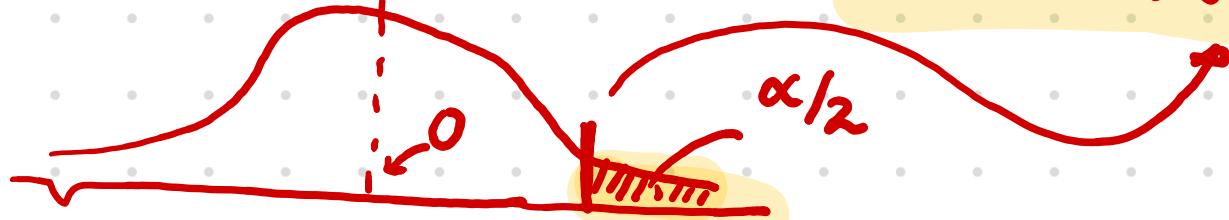

### Confidence interval for $\mu$ under normality

Suppose  $X_1, X_2, \dots, X_n$  are  $N(\mu, \sigma^2)$  distributed.

Let  $\bar{X}$  and  $S^2$  denote the sample mean and sample variance respectively.

We proved that  $T = (\bar{X} - \mu) / (S/\sqrt{n})$  has a t-distribution with  $n-1$  degrees of freedom.

For  $0 < \alpha < 1$ , define  $t_{\alpha/2, n-1}$  to be the value of  $T$  such that  $P(T > t_{\alpha/2, n-1}) = \alpha/2$ .

∴ -

$$1 - \alpha = P(-t_{\alpha/2, n-1} < T < t_{\alpha/2, n-1})$$

$$= P\left(-t_{\alpha/2, n-1} < \frac{\bar{X} - \mu}{S/\sqrt{n}} < t_{\alpha/2, n-1}\right)$$

$$= P\left(-t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} < \bar{X} - \mu < t_{\alpha/2, n-1} \frac{S}{\sqrt{n}}\right)$$

$$= P\left(\bar{X} - t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} < \mu < \bar{X} + t_{\alpha/2, n-1} \frac{S}{\sqrt{n}}\right)$$

∴

$$1 - \alpha = P(-t_{\alpha/2, n-1} < T < t_{\alpha/2, n-1})$$

$$= P\left(-t_{\alpha/2, n-1} < \frac{\bar{X} - \mu}{S/\sqrt{n}} < t_{\alpha/2, n-1}\right)$$

$$= P\left(-t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} < \bar{X} - \mu < t_{\alpha/2, n-1} \frac{S}{\sqrt{n}}\right)$$

$$= P\left(\bar{X} - t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} < \mu < \bar{X} + t_{\alpha/2, n-1} \frac{S}{\sqrt{n}}\right)$$

Once the sample is drawn, let  $\bar{x}$  and  $s$  denote the sample mean and sample variance.

Then a  $(1-\alpha)100\%$  confidence interval of  $\mu$  is given by  $(\bar{x} - t_{\alpha/2, n-1} \frac{s}{\sqrt{n}}, \bar{x} + t_{\alpha/2, n-1} \frac{s}{\sqrt{n}})$ .

## Example.

nhtemp is a dataset in R

t.test(nhtemp, conf.level = 0.99)

## Example.

`nhtemp` is a dataset in R

`t.test(nhtemp, conf.level = 0.99)`

Confidence Interval for Proportion of  $X \sim \text{Ber}(1, p)$

and  $X_1, X_2, \dots, X_n$  is a random sample. Then  $\bar{X}$  is the proportion of successes. With the large sample assumption, this comes to

$$\left( \hat{p} \pm z_{\alpha/2} \sqrt{\hat{p}(1-\hat{p})/n} \right)$$

## Example.

`nhtemp` is a dataset in R

`t.test(nhtemp, conf.level = 0.99)`

### Confidence Interval for Proportion

of  $X \sim \text{Ber}(1, p)$

and  $X_1, X_2, \dots, X_n$  is a random sample. Then  $\bar{X}$  is the proportion of successes. With the large sample assumption, this comes to

$$\left( \hat{p} \pm z_{\alpha/2} \sqrt{\hat{p}(1-\hat{p})/n} \right)$$

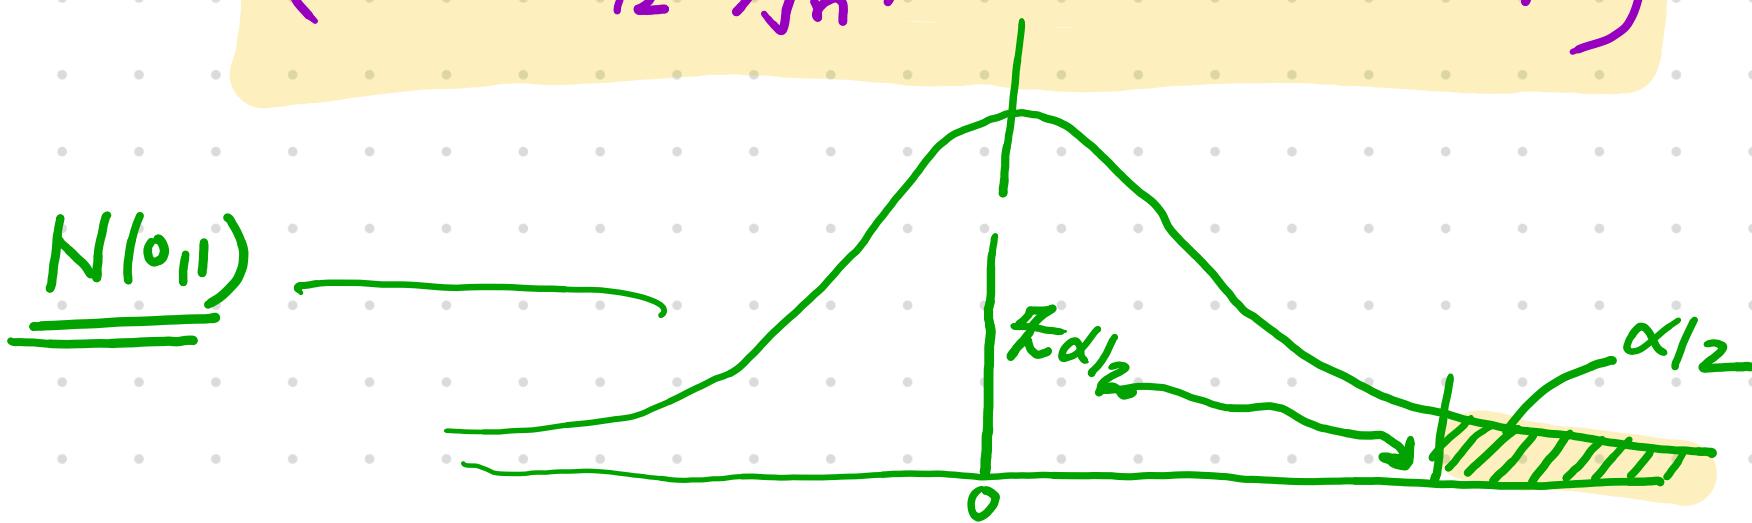

If there are 28 successes in 143, we

`prop.test(28, 143, conf.level = 0.99)`

This is based on the normality of the distribution.

If normality is not known but sample is large, we may use CLT to find approximate confidence intervals.

$$(\bar{x} - z_{\alpha/2} s/\sqrt{n}, \bar{x} + z_{\alpha/2} s/\sqrt{n})$$

## Confidence Intervals for Difference in Means

How to compare means of  $X$  and  $Y$ ?

Let the means be  $\mu_1$  and  $\mu_2$  respectively.

We will obtain confidence intervals for the difference  $\Delta = \mu_1 - \mu_2$ . Assume that  $\sigma_1^2$  and  $\sigma_2^2$  are variances of  $X$  and  $Y$  respectively. Let  $X_1, X_2, \dots, X_n$  be a random sample from  $X$  and  $Y_1, Y_2, \dots, Y_n$  be a random sample from  $Y$ .

$$\bar{X} = \frac{\sum X_i}{n}, \quad \bar{Y} = \frac{\sum Y_i}{n}, \quad \hat{\Delta} = \bar{X} - \bar{Y}.$$

$\hat{\Delta}$  is an unbiased estimator.

The difference  $\hat{\Delta} - \Delta$  will be the numerator of the pivot variable.

By independence,  $\text{Var}(\hat{\Delta}) = \frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}$

Let  $S_1^2 = \frac{\sum_{i=1}^{n_1} (X_i - \bar{X})^2}{n_1 - 1}$

and  $S_2^2 = \frac{\sum_{i=1}^{n_2} (Y_i - \bar{Y})^2}{n_2 - 1}$

We can consider the pivot variable  
approximate

$$Z = \frac{\hat{\Delta} - \Delta}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

whence an  $\int$  confidence interval

is given by

$$\left( (\bar{x} - \bar{y}) - Z_{\alpha/2} \sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}, (\bar{x} - \bar{y}) + Z_{\alpha/2} \sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}} \right).$$

As an example, let us compute an exact confidence interval when  $X$  and  $Y$  are normal with the same variance,  $\sigma_1^2 = \sigma_2^2$ .

As an example, let us compute an exact confidence interval when  $X$  and  $Y$  are normal with the same variance,  $\sigma_1^2 = \sigma_2^2$ . Let  $X \sim N(\mu_1, \sigma^2)$  and  $Y \sim N(\mu_2, \sigma^2)$ .

Note that

$$\frac{(\bar{X} - \bar{Y}) - (\mu_1 - \mu_2)}{\sigma}$$

$$\sqrt{\frac{1}{n_1} + \frac{1}{n_2}}$$

has  $N(0,1)$  distribution.

This will be the numerator of our pivot variable.

Consider

$$S_p = \frac{(n_1-1)S_1^2 + (n_2-1)S_2^2}{n_1 + n_2 - 2}$$

which is a

weighted average of  $S_1$  and  $S_2$ .

Consider

$$S_p = \frac{(n_1 - 1) S_1^2 + (n_2 - 1) S_2^2}{n_1 + n_2 - 2}$$

which is a

weighted average of  $S_1$  and  $S_2$ . (Check  
that this is an unbiased estimator for  $\sigma^2$ ).

Consider

$$S_p = \frac{(n_1-1)S_1^2 + (n_2-1)S_2^2}{n_1 + n_2 - 2}$$

which is a weighted average of  $S_1$  and  $S_2$ . (Check

that this is an unbiased estimator for  $\sigma^2$ ).

Now,  $\frac{(n_1-1)S_1^2}{\sigma^2}$  has a  $\chi^2(n_1-1)$  distribution

$\frac{(n_2-1)S_2^2}{\sigma^2}$  has a  $\chi^2(n_2-1)$  distribution

Consider

$$S_p = \frac{(n_1-1)S_1^2 + (n_2-1)S_2^2}{n_1 + n_2 - 2}$$

which is a

weighted average of  $S_1$  and  $S_2$ . (Check

that this is an unbiased estimator for  $\sigma^2$ ).

Now,

these are  
independent

$\left\{ \begin{array}{l} \frac{(n_1-1)S_1^2}{\sigma^2} \text{ has a } \chi^2(n_1-1) \text{ distribution} \\ \frac{(n_2-1)S_2^2}{\sigma^2} \end{array} \right.$

$\left. \begin{array}{l} \\ \text{has a } \chi^2(n_2-1) \text{ distribution} \end{array} \right.$

Consider

$$S_p^2 = \frac{(n_1-1)S_1^2 + (n_2-1)S_2^2}{n_1 + n_2 - 2}$$

which is a

weighted average of  $S_1$  and  $S_2$ . (Check  
that this is an unbiased estimator for  $\sigma^2$ ).

Now,

these are independent {

$$\frac{(n_1-1)S_1^2}{\sigma^2} \text{ has a } \chi^2(n_1-1) \text{ distribution}$$
$$\frac{(n_2-1)S_2^2}{\sigma^2} \text{ has a } \chi^2(n_2-1) \text{ distribution}$$

$$\therefore \frac{(n-2)S_p^2}{\sigma^2} \text{ has a } \chi^2(n-2) \text{ distribution.}$$

Due to the independence of  $S_1^2$  and  $\bar{X}$ ,

$S_2^2$  and  $\bar{Y}$ , and the independence of the

samples,  $S_p^2$  is independent of

$\bar{X} - \bar{Y}$ .

Due to the independence of  $S_1^2$  and  $\bar{X}$ ,  
 $S_2^2$  and  $\bar{Y}$ , and the independence of the  
samples,  $S_p^2$  is independent of  
 $\bar{X} - \bar{Y}$ . Therefore, the statistic

$$T = \frac{[\bar{X} - \bar{Y}] - (\mu_1 - \mu_2)}{\sigma \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \quad \text{under} \\ \sqrt{(n-2) S_p^2 / (n-2) \sigma^2}$$

$$= \frac{(\bar{X} - \bar{Y}) - (\mu_1 - \mu_2)}{\sqrt{S_p^2 \left( \frac{1}{n_1} + \frac{1}{n_2} \right)}} \quad \sim t_{n-2}$$

This gives us a confidence interval

$$\left( (\bar{x} - \bar{y}) - t_{\alpha/2, n-2} s_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}, (\bar{x} - \bar{y}) + t_{\alpha/2, n-2} s_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}} \right)$$

This gives us a confidence interval

$$(\bar{x} - \bar{y}) - t_{\alpha/2, n-2} s_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}, (\bar{x} - \bar{y}) + t_{\alpha/2, n-2} s_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}$$

install.packages("remotes")

```
remotes::install_github("joemckean/mathstat",
                        force = TRUE)
```

require(mathstat)

hitht = bb\$height[bb\$hitpitind == 1]

pitht = bb\$height[bb\$hitpitind == 0]

t.test(pitht, hitht, var.equal = T)

## Confidence Interval for Variance.

Let  $x_1, x_2, \dots, x_n$

be a random sample from  $N(\mu, \sigma^2)$  where both are unknown.

$\frac{(n-1)S^2}{\sigma^2}$  is a random variable with a  $\chi^2(n-1)$  distribution.

Find 'b' so that  $P((n-1)S^2/\sigma^2 < b) = 0.975$

$$b = q_{\text{chi sq}}(0.975, n-1)$$

## Confidence Interval for Variance.

Let  $x_1, x_2, \dots, x_n$

be a random sample from  $N(\mu, \sigma^2)$  where both are unknown.

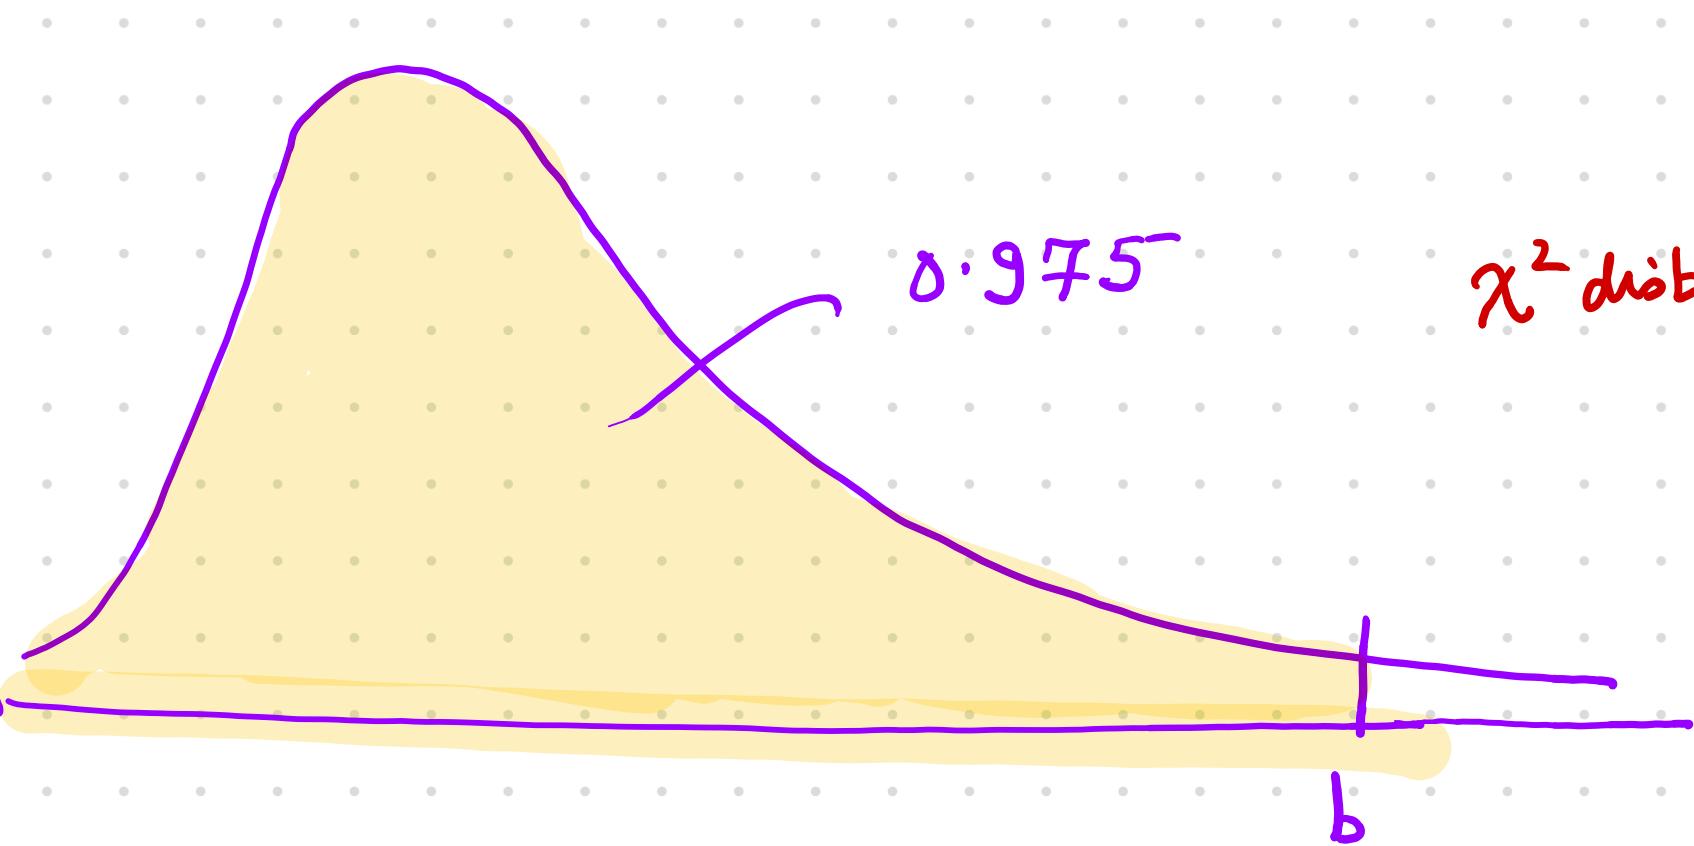

$\frac{(n-1)S^2}{\sigma^2}$  is a random variable with a  $\chi^2(n-1)$  distribution.

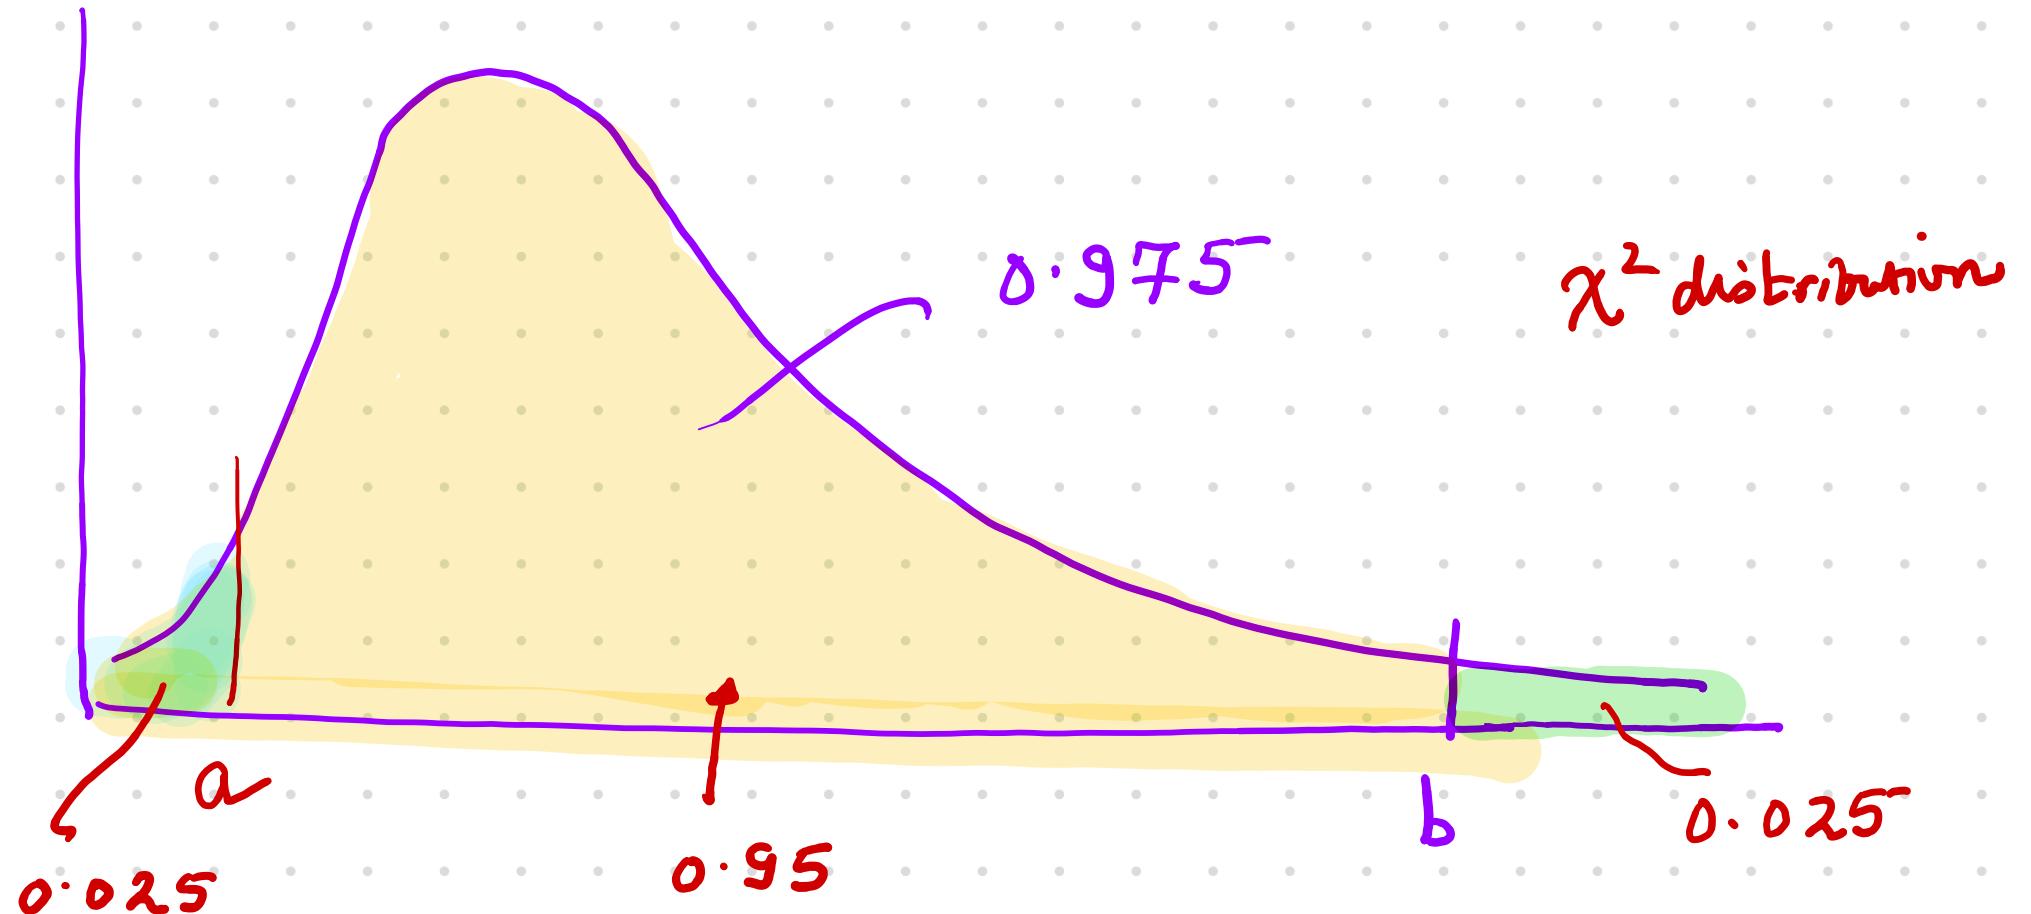

Find 'b' so that  $P\left(\frac{(n-1)S^2}{\sigma^2} < b\right) = 0.975$

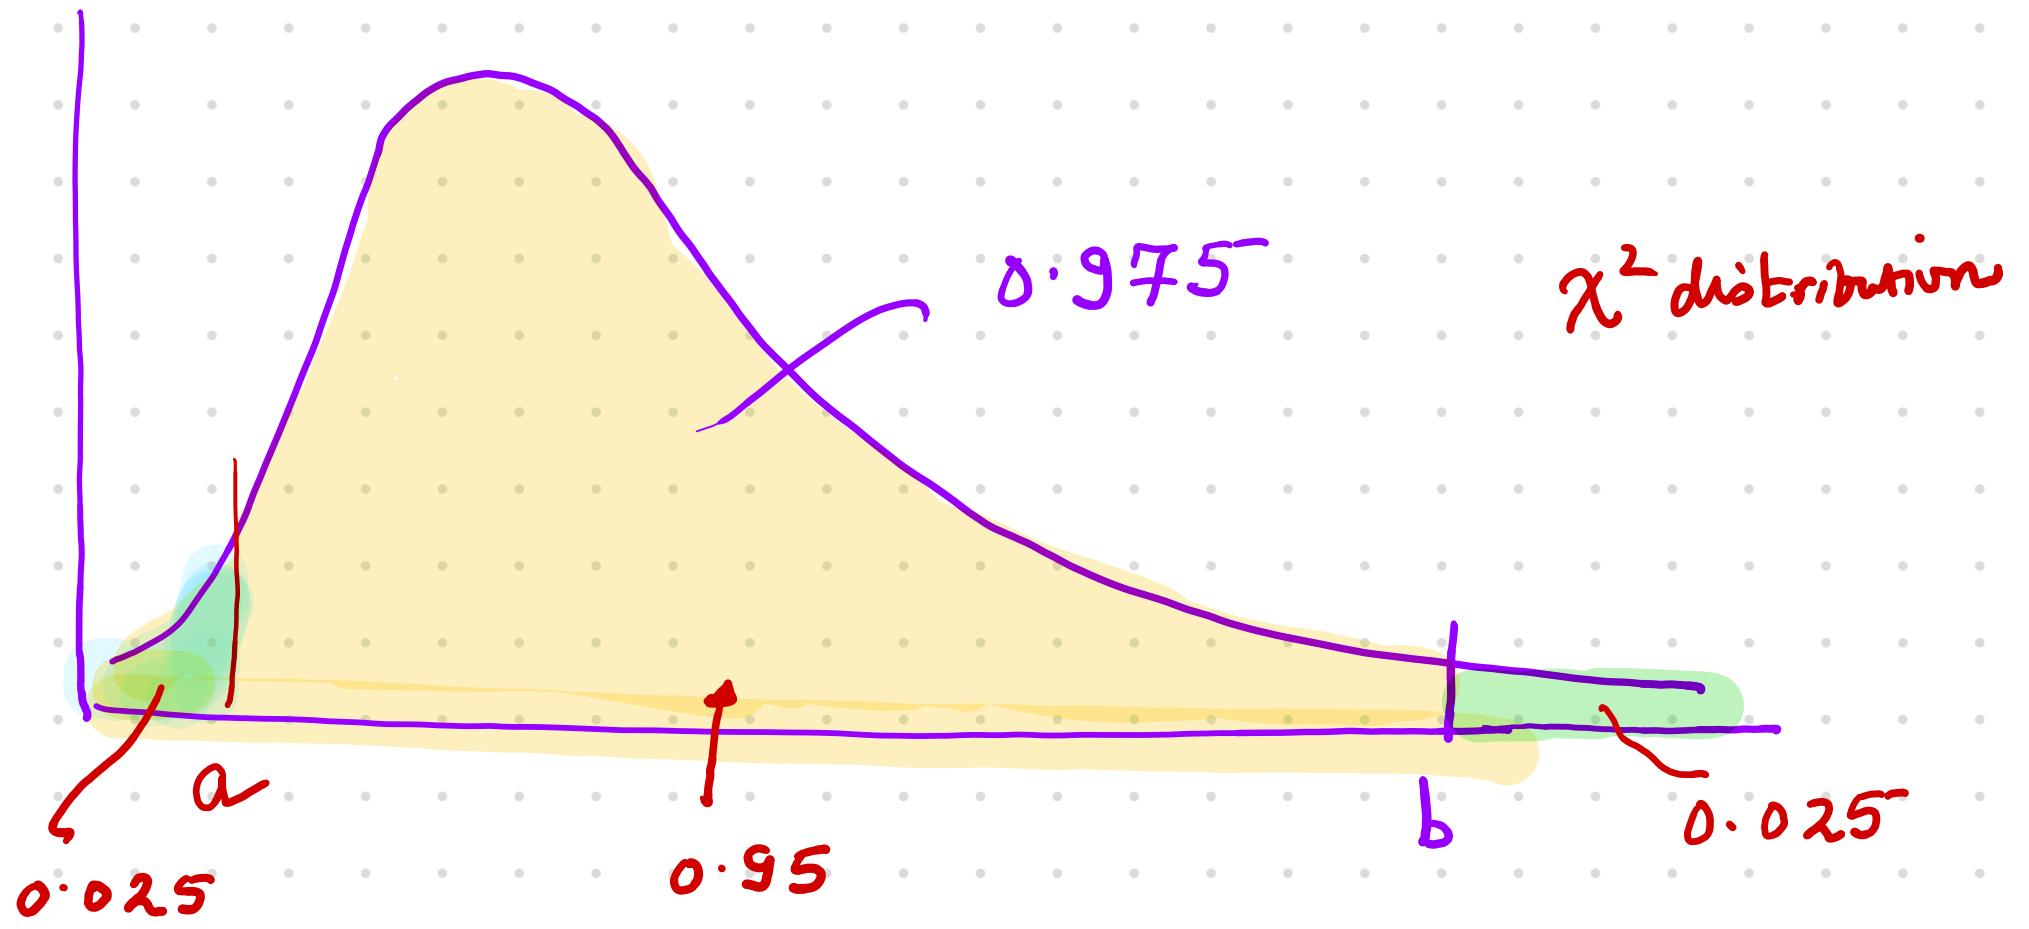

$$b = q_{\text{chisq}}(0.975, n-1)$$

Find 'a' so that  $P\left(a < \frac{(n-1)S^2}{\sigma^2} < b\right) = 0.95$

$$a = q_{\text{chisq}}(0.025, n-1)$$

This is the same as

$$P\left(\frac{(n-1)S^2}{b} < \sigma^2 < \frac{(n-1)S^2}{a}\right) = 0.95$$

Q. If  $n=9$  and  $S^2=7.93$ , find a 95% confidence interval for  $\sigma^2$ .
